

# Including CKMR in stock assessments: The SBT experience

Rich Hillary,  
CSIRO Oceans & Atmosphere

November 16, 2021

# SBT biology & fishery

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Southern bluefin tuna (SBT) 1 of 3 global pop<sup>n</sup>s
- Reasonably fast growing *and* long-lived (30+)
- Late maturing (50% between 8 to 10 y.o.)
- Caught from 2 y.o. onwards by variety of gears/fleets
- Distributed across SEIO, South Atlantic, Tasman Sea

# SBT spawning behaviour

- Spawning (blue), summer ages 2 to 4 (orange):

# Why did we choose SBT for CKMR?

- Status of stock in 2006:
  - 1 Spawning stock biomass (SSB) at 5% of unfished
  - 2 Fishing mortality too high for SSB to increase
  - 3 Weakest recruitments ever seen 1999–2002
  - 4 Substantial historic catch misreporting revealed
- Estimates of  $SSB_{2006}$  **highly** uncertain
- Catch uncertainty essentially unresolvable
- No other plausible data sources to inform on SSB
- CKMR proposed as a viable way to resolve this

# Parent-Offspring Pairs (POPs)

- Adult-juvenile comparisons (looking for POPs)

Abundance from matching up parents & offspring

5 | Close-kin abundance: SBT | MV Bravington

# Parent-Offspring Pairs (POPs)

Including  
CKMR in  
stock

assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Cartoon population dynamics:  $N_A$  is adult abundance
- Genotype  $m_A$  adults &  $m_J$  juveniles
- Chance of finding a parent (mother or father):

$$\mathbb{P}(POP) = \frac{2}{N_A}$$

- You find  $R$  POPs (recaptures basically...)
- Estimate of abundance:  $\hat{N}_A = 2m_A m_J / R$
- Precision: CV will be approximately  $1/\sqrt{R}$
- **Bonus point:** CV scales with  $m_A + m_J$  (not square root)

# Parent-Offspring Pairs (POPs)

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Reality more complex than cartoon...
- Bigger/older adults more successful at reproducing
- Factor age (size) into POP probabilities
- Key covariates in SBT case:
  - 1 Juvenile's year of birth/cohort
  - 2 Adult's sampling year
  - 3 Adult's sampling age/size

# Half-Sibling Pairs (HSPs)

Including  
CKMR in  
stock

assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Juvenile-juvenile comparisons
- You never see the adult
- “Mark”: birth of older juvenile
- “Recapture”: detection of HSP
- Cartoon:  $N_{\sigma} = N_{\text{♀}} = N_A/2$ , mortality  $M_A$
- HSP with a 5 year gap between birth years:

$$\mathbb{P}(\text{HSP}) = \frac{e^{-5M_A}}{N_{\sigma}} + \frac{e^{-5M_A}}{N_{\text{♀}}} = 4 \times \frac{e^{-5M_A}}{N_A}$$

- HSPs have mortality *and* abundance information

# Half-Sibling Pairs (HSPs)

- Again, the cartoon gives way to reality...
- Juvenile-juvenile comparisons:
  - 1 Juvenile cohort,  $c$ , when spawned
  - 2 Covariates:  $\{i, i'\}$ ,  $z_i = \{c_i\}$  and  $z_{i'} = \{c_{i'}\}$
  - 3 **Don't** do within-cohort ( $c_i \neq c_{i'}$ )
- Factors accounted for in  $\mathbb{P}(K_{ii'} = HSP \mid z_i, z_{i'})$ :
  - 1 Unknown adult ages ( $y = c_{\min} = \min\{c_i, c_{i'}\}$ )
  - 2 Cumulative **total** mortality ( $y = c_{\min}, \dots, c_{\max}$ )
  - 3 Increased reproductive output ( $y = c_{\min}, \dots, c_{\max}$ )
  - 4 Time-varying nature of adult abundance
- Eqn<sup>s</sup> more complex than POP case (see me later...)

# Why POPs **and** HSPs?

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Can't do it all with just POPs
- Disentangling abundance, mortality and age/size
- Having both can undo this demographic Gordian knot
- Able to test key assumptions (e.g. pop<sup>n</sup> structure)
- Reduce sample sizes (you already have the juveniles...)
- Question really is why *wouldn't* you do both

# SBT CKMR “timeline”

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Idea proposed in late 2000s
- **Phase 1:**
  - Use microsattellites; POPs only
  - Incorporated in SBT assessment 2012
- **Phase 2:**
  - Move to SNPs; both POPs & HSPs
  - Both incorporated in SBT assessment 2017
- CKMR included in revised Management Procedure (2020)

# Sample sizes

- Number required depends on  $\text{pop}^n$  size
- Also depends on what you want from the data
- Since 2006:
  - **Adults:** almost 10,000 genotyped
  - **Juveniles:** just over 15,000 genotyped
  - Around 25,000 fish in total: 89 POPs; 115 HSPs
  - Data covers over 10 years of adult dynamics
  - Current rate: about 1,000 adults, 1,000 juveniles *p.a.*
- Sample harder early: accrue matches slowly then quickly
- Later on modify according to needs/resources

# SBT stock assessment structure

Including  
CKMR in  
stock

assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Data sources:
  - 1 Age/length catch composition
  - 2 Longline CPUE index (mostly on sub-adults)
  - 3 Multi-year mark-recapture (juveniles  $a = 2, \dots, 5$ )
  - 4 Juvenile (ages 2–4) relative biomass survey
  - 5 Gene-tagging 2 year old absolute abundance index
  - 6 CKMR (POPs and HSPs)
  
- Model structure: “standard” age and seasonal model
  
- Key parameters:
  - 1 Annual recruitment
  - 2 Time-varying fishery selectivity
  - 3 Age-dependent natural mortality
  - 4 Length-specific reproductive output ( $\psi$ )

# Summary of the POP data

- 1 Years (2006–2018), cohorts (2002–2015), age (5+)
- 2 Around 112 **million** comparisons; 89 POPs

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

# Summary of the HSP data

1 Cohorts (2003–2012)

2 Around 88 million comparisons; 115 HSPs

# Key reproductive pop<sup>n</sup> variables

- Relative TRO (top) & mean age in spawners (bottom):

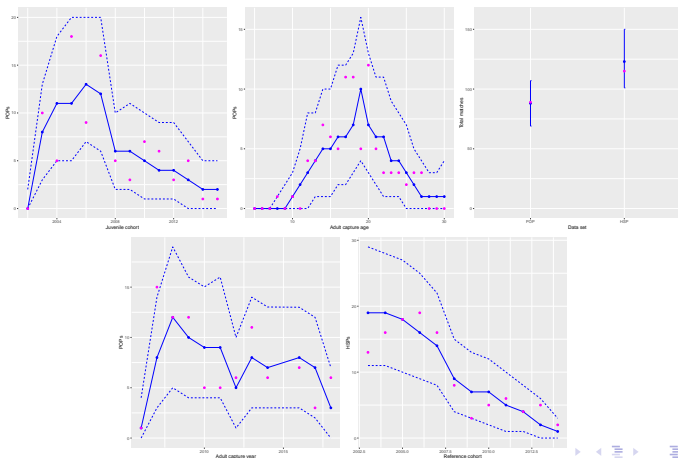

# Fits to the CKMR data

- Data (esp. POPs) basically sparse MR data
- Aggregate data/predictions across covariates
- POP data aggregation:
  - 1 Adult capture age & year (cohort level)
  - 2 Adult capture age & juvenile cohort (age level)
  - 3 Adult capture age and cohort (adult sampling year level)
- HSP data aggregation:
  - 1 Following juvenile cohort (initial cohort level)

# Fits to the CKMR data

- POP cohort (TL), age (TM), year (BL) level; HSP (BR) initial cohort and finally total matches (TR):

# What did the CKMR change/tell us?

- Spawning population larger, less depleted
- Current depletion: 0.2 (0.16–0.24)
- Sustainable yields essentially unchanged
- Adult mortality lower than previously thought
- Successful sizes/ages of reproduction bigger/older
- However, Big Fecund Female hypothesis not supported

# Oversight & engagement

Including  
CKMR in  
stock  
assessments:  
The SBT  
experience

Rich Hillary,  
CSIRO  
Oceans &  
Atmosphere

- Original project had expert steering committee
- Move from microsats to SNPs reviewed by experts
- Get buy-in from stakeholders, SC and Commission
- Particularly on genetics - topic of least familiarity

# Lessons learned & future work

- Unsurprisingly, this takes time...
- Takes a dedicated inter-disciplinary team
- Important to explore role of length/sexual dimorphism
  - SBT seems OK; exception not the rule?
- Spend **a lot** of time bringing people along
- CCSBT funded CKMR as ongoing monitoring program
- CKMR data used in CCSBT Management Procedure

# Acknowledgements
