

We would like to request that the ISC provide estimates of the historical impact of each fleet group (fleet groups defined in WCPFC-NC21-2025/WP-07) on the stock, based on fishing intensity during the time periods of 2002-2004 and 1999-2015 to guide the fleet-specific reductions in fishing intensity should the female spawning stock biomass (SSB) fall below the threshold reference point ( $30\%SSB_{current, F=0}$ ), as mandated by the harvest strategy harvest control rules.

These fleet-specific reductions of total fishing intensity could then, in turn, be converted into management metrics such as catch, and/or effort levels, as might be needed for future discussions.
