ESTIMATES OF ANNUAL CATCHES IN THE WCPFC STATISTICAL AREA

Oceanic Fisheries Programme
Secretariat of the Pacific Community
Noumea, New Caledonia

July 2008

INTRODUCTION

Estimates of annual catches in the WCPFC Statistical Area (Figure 1) are presented for target tuna species, i.e., albacore (*Thunnus alalunga*) bigeye (*Thunnus obesus*), skipjack (*Katsuwonus pelamis*) and yellowfin (*Thunnus albacares*), and major billfish species, i.e., black marlin (*Makaira indica*), blue marlin (*Makaira mazara*), striped marlin (*Tetrapturus audax*) and swordfish (*Xiphias gladius*). Estimates of discards of target tunas and catches in recent years of other non-target fish species, determined from observer data, are also presented. Estimates of catches of southern bluefin tuna (*Thunnus maccoyii*), which are compiled by the Commission for the Conservation of Southern Bluefin Tuna (CCSBT), and catches of small tunas in the domestic fisheries of Indonesia and the Philippines are not presented. Recent catches of tuna in the domestic fisheries of Vietnam may have amounted to about 19,000 tonnes of skipjack, 18,000 tonnes of yellowfin and 5,500 tonnes of bigeye, for a total of 42,500 tonnes (Lewis 2005); however, these catches have been ignored in the tables and figures presented below. The compilation of estimates of catches of Pacific bluefin tuna (*Thunnus orientalis*) commenced only recently; estimates for Pacific bluefin will be presented in future editions of this report.

TARGET TUNA SPECIES

Tables 1–3 and Figures 2 and 3 present estimates of annual catches of target tunas in the WCPFC Statistical Area. For the sources of the annual catch estimates, see Lawson (2007a). For discussion regarding trends, see Williams & Reid (2008). Estimates of purse-seine catches of bigeye and yellowfin that were not already adjusted for the misidentification of bigeye as yellowfin have been adjusted by the OFFP (Lawson 2007b). Estimates for 2006–2007 are preliminary.

Notable revisions to the catch estimates include an increase in the estimated catch of bigeye in 2006 from 117,143 t reported last year to 135,726 t reported this year, and a increase in the yellowfin catch in 2006 from 401,773 t to 442,288 t. The changes in both bigeye and yellowfin are due to upward revisions for longline, pole-and-line and purse seine.

Tables 4–7 present estimates of annual catches of target tunas in the WCPO Area and the EPO Area (Figure 1) by gear type. Tables 8–10 present estimates of annual catches of target tunas for the WCPO, the EPO and the Pacific Ocean by species. Table 11 and 12, and Figures 4 and 5, present global catches of target tunas, by species and ocean area respectively.

DISCARDS

An analysis of variance of discard rates for albacore, bigeye and yellowfin and bigeye caught by longliners, determined from observer data stratified by trip, indicated that species, year and flag were significant predictors. Discards by longliners in the WCPFC Statistical Area during 1994–

2006 were estimated with the predicted discard rates; the estimates are presented in Table 13. For flags for which no observer data are available to predict discard rates, discard rates averaged over all other flags, for the species and year, were used. The total discard rate for the three target tuna species during the period was 3.5%.

An analysis of variance of discard rates for skipjack, yellowfin and bigeye caught by purse seiners, determined from observer data stratified by trip, indicated that species, school association (associated or unassociated) and flag, but not year, were significant predictors. Discards by purse seiners in the WCPFC Statistical Area, from 20°S to 20°N and excluding the domestic fisheries of Indonesia and the Philippines, during 1995–2007, were estimated with the predicted discard rates; the estimates are presented in Table 14. The total discard rate for the three target tuna species during the period was 5.0%.

MAJOR BILLFISH SPECIES

Table 15 presents estimates of commercial catches of the four major billfish species by gear type. Table 16 and Figure 6 present estimates of the major billfish catches for all gear types combined. Tables 17 and 18 present estimates of commercial catches of striped marlin and swordfish in the WCPFC Statistical Area north and south of the equator respectively.

OTHER NON-TARGET SPECIES AND SPECIES GROUPS

Estimates of annual catches of other non-target species and species groups were determined from observer data held by the SPC Oceanic Fisheries Programme. Tables 19 and 20 present statistics on observer coverage of longliners and purse seiners. No observer data are available for the domestic fisheries of Indonesia, the Philippines and Chinese Taipei; hence, the catch estimates exclude these sectors.

For longline, observer coverage from 1992 to 2007 has been 0.72% of total effort. Distant-water fleets accounted for 58%, 38% and 58% of the longline catch of albacore, bigeye and yellowfin in the WCPFC Statistical Area during 1992–2007 respectively; however, coverage of the distant-water longline fleets by data held by the OFP is less than 0.06%. Observer data covering the Hawaii longline fleet during 2005–2007 were not yet available at the time of the analysis.

For purse-seine, observer coverage from 1994 to 2007 has been 5.32%. Coverage rates have increased from 2002 onwards due to higher coverage of the fleets of the FSM Arrangement, including Federated States of Micronesia, Marshall Islands, Papua New Guinea, Solomon Islands and Vanuatu. Coverage rates for sets on unassociated and associated schools have been similar.

Catches for each non-target species or species group were estimated using model-based predictors of the catch rate. The logistic and lognormal components of a zero-inflated lognormal (ZILN) model were fitted with the ‘glm’ function in R¹. For longline, the predicted variable was the logarithm of the catch rate for the observed trip, and predictors were year, month, the number hooks between floats (a proxy for depth), latitude, longitude, sea surface salinity, sea surface temperature and the depth of the 20°C isotherm. For purse seine, the predicted variable was the logarithm of the catch

¹ R Development Core Team. 2007. R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria. ISBN 3-900051-07-0, URL <http://www.R-project.org>.

rate for the observed trip, and predictors were school association (associated or unassociated), year, month, latitude, longitude, sea surface salinity, sea surface temperature and the depth of the 20°C isotherm. All numerical predictors were smoothed with cubic splines. The inclusion of predictors in the model, and the degrees of freedom for the smoothed predictors, were determined using a stepwise procedure that minimised the Bayesian information criterion (BIC). The degrees of freedom and other statistics for each of the models for longline and purse seine are presented in SPC (2007).

The ZILN models of catch rates were applied to stratified effort data. For longline, effort data for the WCPFC Statistical Area were stratified by year, month, 5° of latitude and 5° of longitude; for each time-area stratum, averages of the number of hooks between floats and the oceanographic variables were determined. For purse seine, effort data for the area bounded by 130°E, 150°W, 20°N and 20°S were stratified by year, month, 2° of latitude, 5° of longitude and school association (associated or unassociated); for each time-area stratum, averages of the oceanographic variables were determined. Confidence intervals for the catch estimates were determined from a parametric bootstrap, i.e., from the 2.5% and 97.5% quantiles of catches estimated by taking 1,000 random samples from the posterior distributions of estimates of the model coefficients; the median was taken to be the point estimate. The confidence intervals do not account for errors in the estimates of total effort and model uncertainty, hence they underestimate the true uncertainty.

Catch estimates for longline and purse-seine are presented in Tables 21 and 22 respectively. Figures 7 and 8 present estimated catches and catch rates for non-target species caught by longline and purse seine respectively. The following points were noted in SPC (2007):

- For longline, latitude and longitude are the most important predictors of catch rate, followed by year, sea surface temperature and the number of hooks between floats. For purse seine, longitude is the most important predictor, followed by year, school association and latitude.
- The average degrees of freedom of model predictors and deviance explained was 17.6 and 34.4% respectively for longline, and 4.1 and 16.8% respectively for purse seine. The larger values for longline reflect the broader geographic area and variation in catch rates compared to purse seine.
- For longline, sector was a significant predictor in the logistic component for three species or species groups, in the lognormal component for three, in both for five and in neither for six. For those species or species groups for which sector is significant, the estimates of catch rates could be improved by including sector as a predictor; however, doing so would almost certainly introduce bias into the estimates for the two distant-water sectors, which are covered by only 12 observed trips over the entire time series.
- The estimated catch rates for longline differ considerably from observed catch rates, particularly for individual year-sector strata. For the distant-water longline fleets in particular, for which observer data are lacking, the estimated catch rates are, for many species or species groups, unreasonably high or low. The catch estimates in Table 21 and Figure 7 should therefore be considered only as roughly indicative.
- Low values of observed and estimated catch rates for silky shark caught by longliners in 1994 may be due to species identification errors during the initial implementation of observer programmes covering the offshore tropical sector. Species identification errors may also be responsible for the low values of observed and estimated catch rates for oceanic whitetip sharks and silky sharks caught by purse seiners, and high values for ‘other sharks and rays’, during the early period of the time series. Data quality in observer programmes covering offshore longline

and purse seine increased considerably from 1995 onwards through technical support provided by the South Pacific Regional Tuna Resources Assessment and Monitoring Project of SPC.

Figure 9 presents the species group composition in the WCPFC Statistical Area (excluding the domestic fisheries of Indonesia, the Philippines and Chinese Taipei) during 1995–2006 for longliners and purse seiners.
